Kumiho Revka 9miho

Everything's running (the `revka memory` calls just hang — a Revka quirk, not a dead stack). I have what I need to answer clearly.

The three apps, in plain English

Think of it as a filing cabinet, a manager, and a production studio.

Kumiho = the filing cabinet. It remembers things as a web of connections — not rows in a table. "This shot → this speaker → this wedding → this client's preferences." It's the only one that stores anything long-term.

Revka = the manager. It decides what to do, calls tools, talks to you, and writes down what it learns. It already treats Kumiho as its memory. It also handles approvals, budgets, safety rules and audit trails.

9miho = the production studio. 91 creative tools — text-to-video, image generation, voiceovers, music, upscaling, timelines. It makes the actual footage.

The gap: the studio and the filing cabinet aren't talking. 9miho's graph link is switched off (`tenant_configured: false`). So the video it makes never becomes something Kumiho can remember.

Videos worth watching

These are the two closest to what you're building:

🎥 Road to NODES AI: Graph-Based Long-Term Memory — a talk on exactly your idea: agentic workflows that adapt through experience via a graph. Best single "this is the vision" watch.

🎓 Neo4j Agent Memory Workshop (free, 3h20m, 11 lessons) — the practical build. It covers reasoning traces — storing why the agent decided something — which is the part most people skip and the part that makes graphs trustworthy. Very close to what you described.

One honest note: the Neo4j workshop uses Neo4j directly, not Kumiho. Same underlying ideas, different wrapper — the concepts transfer to what we're running.

What we actually have (the honest part)

I checked the live databases rather than assuming:

```
Kumiho graph:   15 nodes, 14 relationships
                (5 Spaces, 2 Projects, 2 UserRoles, 1 Tenant, 1 User, 1 Item)
9miho assets:   [] — empty
```

So the plumbing is built and healthy, but it's essentially empty. The relationship-graph-everything vision is real and the machine is ready — there's just nothing in it yet. That's actually good news: no migration debt.

What to do next, with actual data

Step 1 — Turn on the 9miho → Kumiho bridge. This is the single highest-leverage move. It configures 9miho's tenant so every asset, approval and lineage edge it creates gets written into the graph. Without it, everything downstream is blocked — the studio's output stays invisible to memory.

Step 2 — Ingest real media. Drop actual footage into 9miho. Once the bridge is on, that footage generates nodes: assets, people, scenes, projects, and the relationships between them. This is when you start seeing the graph.

Step 3 — Enable embeddings (still needs your Cloudflare token). This is what makes it search by meaning rather than by filename. It's the difference between "find `beach_wedding_04.mp4`" and "find the emotional, sunset-beach, father-daughter moment from the Alvarez wedding." Right now embeddings are off, so search is keyword-only.

Step 4 — Point Revka at your video flow. Revka becomes the single agent that both remembers (via Kumiho) and creates (via 9miho). That's the unification you want — not merging apps, but one brain with a memory and a studio.

Step 5 — Light up the VidiFlow graph view. Your `3d-force-graph` renderer is already built in the architecture plan. Point it at Kumiho and the graph you've been imagining appears on screen, live.

The one thing blocking you

Step 3 needs a Cloudflare API token (Workers AI: Read). It's the only thing I genuinely can't do for you. Save it as `KUMIHO_EMBEDDING_API_KEY=<token>` in `C:\Users\James\.kumiho\embedding.key` and re-run `recover-kumiho.ps1`.

Steps 1, 2, 4 and 5 I can do right now.

Want me to start with Step 1 — the 9miho→Kumiho bridge? It's the smallest change that unlocks everything else, and it means the first real footage you drop in starts building your graph immediately.
